Phase Noise and Phase Jitter Integration

Phase noise is measured in the frequency domain, and is expressed as a ratio of signal power to noise power measured in a 1Hz bandwidth at an offset frequency from the carrier, e.g. 10Hz, 100Hz, 1kHz, 10kHz, 100kHz, etc. Phase noise measurement is made with an Agilent E5052A Signal Source Analyzer (SSA) with built-in outstanding low-noise DC power supply source. The DC source is floated from the ground and isolated from external noise to ensure accuracy and repeatability.

In order to determine the total noise power over a certain frequency range (bandwidth), the time domain must be analyzed in the frequency domain, and then reconstructed in the time domain into an rms value with the unwanted frequencies excluded. This may be done by converting $L(f)$ back to $S\phi(f)$ over the bandwidth of interest, integrating and performing some calculations.

Symbol	Definition
$\int L(f)$	Integrated single side band phase noise (dBc)
$S\phi(f) = (180/\pi) \times \sqrt{2} \int L(f) df$	Spectral density of phase modulation, also known as RMS phase error (in degrees)
RMS jitter = $S\phi(f) / (f_{osc} \cdot 360^\circ)$	Jitter (in seconds) due to phase noise. Note $S\phi(f)$ in degrees.

The value of RMS jitter over the bandwidth of interest, e.g. 10kHz to 20MHz, 10Hz to 20MHz, represents 1 standard deviation of phase jitter contributed by the noise in that defined bandwidth.

Figure below shows a typical Phase Noise/Phase jitter of a QCC325, 3.3Vdc, 25MHz clock at offset frequencies 1Hz to 1MHz, and phase jitter integrated over the bandwidth of 12kHz to 1MHz.
